Anthropometry Measurement(s) Body size Sizes (Dimensions)		Survey(s) U. S. Army Military personnel Women	
		Human factors engineering Static strength Data	
This report, the second in a series, summarizes the univariate statistics obtained in an anthropometric survey of women in the U. S. Army conducted at Fort Sam Houston, Texas; Fort McClellan, Alabama; Walter Reed Medical Center, the District of Columbia; and Fort Jackson, South Carolina, during the winter of 1976-1977. This survey, carried out to satisfy the need by the U. S. Army for up-to-date data on the body sizes and strength capabilities of the women who now constitute a substantial portion of its personnel, represents the

20. ABSTRACT (continued)

First major anthropometric survey of Army women since 1946.

Data for 69 body size measurements were obtained on a sample of 1,331 women who covered wide ranges of age, rank, and military assignment. Additional data were obtained on subseries of between 200 and 300 women for: (a) other standard body size measurements, (b) workspace measurements, (c) head and face measurements, and (d) static strength measurements. Summary statistics and frequency distributions are given here for all these measurements, plus age.

Full descriptions of the measurement techniques and the design and conduct of the survey have already appeared in the first of this series of reports. Brief definitions, illustrations of measurements, and outlines of the computational and statistical procedures used in preparing this report are included here.

## PREFACE

This report provides the basic statistical results of an anthropometric survey of Army women. The survey was carried out and this report prepared by the Anthropology Research Project of Webb Associates, Inc., Yellow Springs, Ohio, under contract DAAG17-76-C-0010 with the U. S. Army Natick Research and Development Command, Natick, Massachusetts. Mr. Edmund Churchill acted as senior investigator and Mr. Robert M. White as project officer for the Natick Research and Development Command. Mr. Thomas Churchill was responsible for editing the data and for the computational aspects of this report. Ms. Jane Reese and Ms. Ilse Tebbets undertook the editing, proofreading and final preparation of the report for publication.

Administrative support, without which the survey would have been impossible, was provided at Fort Sam Houston by Colonel Maurice H. Hensley, Colonel George Kreuger, Lieutenant Colonel Robert H. Willis, Captain Dale Coburn, and First Lieutenant Shirley Bolton; at Fort McClellan by Captain Cheryl Crawford and Second Lieutenant Winifred Petterson; at Walter Reed Medical Center by Major Rose Weddell; and at Fort Jackson by Lieutenant Colonel Robert D. Martin and Mr. Gordon Wingard. The authors wish to express once again their thanks to these men and women.

ANTHROPOMETRY OF WOMEN OF THE U. S. ARMY--1977  
REPORT NO. 2 - THE BASIC UNIVARIATE STATISTICS

INTRODUCTION

An anthropometric survey of women wearing the uniform of the U. S. Army—the first such survey since 1946—was carried out during the winter of 1976-1977.

This report is the second of a series dealing with the conduct and results of this survey. The preceding report (Laubach, L.I., J.T. McConville, E. Churchill and R.M. White, Anthropometry of Women of the U.S. Army—1977, Report No. 1 - Methodology and Survey Plan, Technical Report Natick/TR-77/021, U.S. Army Natick Research and Development Command, Natick, Massachusetts, 1977) describes the methodology of the survey and the measuring techniques used in the survey. This report presents the basic statistical results for the entire survey sample and its four subsamples. The subsequent reports will include additional statistical material providing contrasts between major subgroups of the sample, statistics for a number of computed variables, and bivariate and multivariate statistics.

Chapter I describes the survey and the sample; Chapter II outlines the computational procedures used with the survey data and defines the statistics which are reported in this report. Chapter III provides descriptive statistics for the 69 core measurements made on the entire survey sample. Each set of statistics is accompanied by a brief definition of the measurement and a line drawing illustrating it. The next four chapters include similar material for the four sub-series of measurements: a series of traditional anthropometric measures similar to the core series; a series of workspace measurements; a series of head and face measurements; and finally, a series of static muscle strength measurements.

Frequency distributions for all variables are given in Appendix A and XVAL (eXtreme VAalue) printouts in Appendix B. Appendix C contains coding for the background variables (e.g., race, rank, birthplace, etc.). The report ends with an index of measurements by name, anatomical location, and anthropometric technique.

## Chapter I

### THE SURVEY AND THE SAMPLE

The design and conduct of the 1976-1977 survey of women wearing the uniform of the U. S. Army have been described and detailed descriptions of the measuring techniques have been provided by L.L. Laubach, J.T. McCorville, E. Churchill, and R.M. White in the first report on this survey (Anthropometry of Women of the U.S. Army--1977, Report No. 1 - Methodology and Survey Plan. Technical Report Natick/TR-77-021, U.S. Army Natick Research and Development Command, Natick, Massachusetts, 1977). The measurements made were divided into five groups: a basic set of 69 measurements, designated as the core series, which were measured on each subject and four subseries of measurements. Most subjects were measured in one of the following subseries: (a) 28 additional traditional anthropometric measurements; (b) 14 workspace measurements; (c) 31 head and face measurements (in addition to three head and face measurements in the core series); and (d) duplicate measurements of static strength measured with the subjects in nine different situations.

A full list of the measurements is given in Table 1 where we have listed the full name of each measurement and a companion "short" name (up to 18 characters). The short name will be used in many computer-generated tables and appears on the magnetic tape record of the survey data. The variable numbers indicate the sequence in which they appear within the five separate series of measurements. Here the letter "C" denotes a core measurement, "T" a measurement in the traditional anthropometry subseries, "W" a workspace measurement, "H" a head-face measurement, and "S" a static strength measurement. The sequences in which the data for each variable are presented were selected to provide a logical ordering of the measurements, putting the height measurements together, the circumferences together, and so forth. The order of the variables on the measuring blanks (see Figures 1 through 5) on the other hand, was selected to provide an efficient sequence for the measuring process; the desire to keep the number of changes in the subject's position as small as possible, for example, often required the separation in the measurement sequence of measurements which logically belonged together.

One further listing of the measurement names and sequence numbers is given at the end of this report in the "Index by Name, Anatomical Location and Anthropometric Technique." As the name of this index suggests, each measurement appears in this index several times. Tibial height, for example, will be listed by itself, under the heading KNEE along with other measurements made at or to the knee area, and under

the heading HEIGHTS along with all other measurements of this type. Where an anatomical location is designated in this index by its technical name, the common name is often cross referenced and vice versa. Specific points are also often cross referenced to larger areas of which they are a part as, for example, *menton* and *chin*. It is hoped that this index will facilitate the location of measurements whose names are not known exactly and will simplify the determination of whether a specific measurement was or was not made.

Over 1,300 women were measured during the course of this survey. The number of subjects measured at each of the four sites in the core series and each of the subsamples appears in Table 2. No workspace measurements were made at Fort Sam Houston because of problems of space and no head and face measurements at Walter Reed Medical Center due to the lack of a suitable place for mounting the headboard. No traditional anthropometry subsamples measurements were made at Fort Jackson since the subsample of 255 previously measured was deemed adequate.

The socio-military data provided by the survey subjects are summarized in Tables 3 through 10.

Of this sample 344 or about 26% were officers and 987 or about 74% were enlisted women. About two-thirds of the officers were first lieutenants or captains. Nearly half the enlisted women were E-1's and about four-fifths of them were in the three lowest ranks. The distribution by age is shown in Table 4. About 30% of the sample was under 20 years of age, the median age was about 22.5, and the 90th percentile was close to 30 years. Distribution of the sample by race appears in Table 5: 75.2% of the sample were Whites, 22.9% were Blacks, and 1.9% were Orientals. Information on race was not asked of the subjects but was inconspicuously noted on the measurement blank by one of the recorders on the basis of each subject's appearance. No attempt was made to identify Chicanos separately from the Whites.

The distribution of the sample by military occupation is given in Table 6. Subjects were asked to specify their primary and secondary MOS's and to respond to the question, "What is your primary duty?" Responses were sometimes vague, ambiguous, or incomplete. Coding of the military occupations was done on the basis of all the relevant information supplied by the subject. While undoubtedly there are errors in our coding, the distribution appearing in Table 6 in all likelihood presents a reasonably accurate picture of the occupations which the women held or for which they were in training.

As this distribution shows, almost exactly two-thirds of the officer sample were nurses, 20% were student officers, and the remainder were dietitians, company commanders and training officers, therapists, military police, and so forth.

The distribution of the enlisted women falls nicely into three groups of approximately equal sizes: clerical workers (typists and various types of clerks), medical personnel (laboratory technicians, nurses' aides, X-ray, dental, pharmacy, operating room, and medical records specialists or technicians, and so forth), and all others. Of the occupations which make up this third group, only the military police (N=67) constitute a subgroup as large as 5% of the enlisted sample. Cooks (N=38), drill sergeants (N=31), communication specialists (N=25), a miscellaneous group of mechanics, welders, and carpenters (N=18), chaplains' assistants and para-legal aides (N=17), and food inspectors (N=10), make up, in each case, 1% or more of the subsample.

Length of service is summarized in Table 7. While a handful of subjects had been in the Army for over 20 years, about one-third of the subjects had been in for less than two months and two-thirds had been in for less than a year..

Birthplaces are reported in Table 8; in Table 9 we have listed the percentages of the subjects born in each of the standard geographical regions along with the populations of these regions as reported by the Bureau of the Census for 1950 and 1960. Since the median birthdate for our subjects is about halfway between the dates of these censuses, one might expect the sample breakdown to roughly approximate the coverage of these two sets of census figures. In the main, there is a fair agreement, the major differences being an unexpectedly large number of subjects from the south-Atlantic states and a smaller than anticipated number from the mid-Atlantic states. It seems doubtful that these differences would have any meaningful effect on the anthropometric data collected in this survey.

The final table in this group is Table 10 which contains the breakdown by handedness.

Measurements were made at Fort Sam Houston during the period of November 2 through November 16, at Fort McClellan from November 17 through December 3, 1976, at Walter Reed Medical Center from January 8 through January 21, and at Fort Jackson from January 25 through February 11, 1977. No measuring was done between December 3, 1976 and January 8, 1977 because of the anticipated problems in securing subjects during the holiday period. All measurements, except the workspace and strength measurements, were made by Becca Fenton, Jay Frost, Leslie Metcalf, Diana O'Daniel, Becky Sikes, and Elizabeth Wheeler, who had been intensively trained prior to the survey by Drs. Lloyd L. Laubach and John McConville of the Anthropology Research Project with the assistance of Mr. Milton Alexander of the U. S. Air Force Aerospace Medical Research Laboratory. The measurers worked in pairs, alternating

between the roles of measurer and recorder as they saw fit. Each pair was responsible for approximately one-third of the core measurements and one-third of the traditional anthropometry and the head and face subseries. The division of the measurements into the three groups is indicated for the core and traditional anthropometry series on the survey blanks (Figures 1 and 2). The first team made measurements 1-16 of the head and face subseries (those made using the headboard); the second team made the caliper measurements, numbers 17-26; and the third team measured the five arcs, measurements 27-31.

During the first half of the survey the team was directed by Dr. Laubach as field supervisor and Ms. Patricia Reese as team supervisor. Ms. Reese and Dr. Laubach carried out the workspace and strength measurements during this period. For the second half of the program, Ms. Reese carried full responsibility for the direction of the team's activities, and, with the assistance of Ms. Linda Grunwoldt, made all the workspace and most of the strength measurements.

## Chapter II

### STATISTICAL ANALYSIS AND COMPUTATIONAL PROCEDURES

The statistical and computational procedures used in preparing this report are much the same as those used in the analyses of the data from the 1970 survey of Army aviators and the data from the 1968 survey of Air Force women (Clauser, C. E., P. Tucker, J. T. McConville, E. Churchill, L. L. Laubach and J. Reardon. Anthropometry of Air Force Women. AMRL-TR-70-5, Aerospace Medical Research Laboratory, Wright-Patterson Air Force Base, Ohio, 1972, AD 743 113). Our discussion here will follow closely that included in the Army aviator report (Churchill, E., J.T. McConville, L.L. Laubach and R.M. White. Anthropometry of U. S. Army Aviators—1970. Technical Report 72-52-CE, U. S. Army Natick Laboratories, Natick, Massachusetts, 1971. AD 743 528).

#### Statistical Analysis

The statistical measures used here to summarize the survey data were chosen as being the univariate statistics which should provide most potential users of the data with the maximum of useful information. They are, in the main, those statistics which have become traditional in anthropometric reports prepared by the U. S. Army and the U. S. Air Force.

Briefly described, the statistics provided for each measurement are the following:

1. The arithmetic mean. This is the most common of the averages and is computed as the sum of the values divided by the number of values. It is usually designated as  $M$ ,  $\bar{x}$ , or  $\mu$ . Any one of these symbols may be subscripted when several variables are considered simultaneously.

2. The median. A second average, the median, designates the value of the "person-in-the-middle." If all the subjects in this survey had been lined up in order from the shortest to the tallest, the height of the subject in the middle of the line would be the median height. The definition of the median is the same as that of the 50th percentile—half of the data being smaller than the median and half being larger. The value of the median is to be found at the middle of the percentile tables.

The median and the arithmetic mean have approximately the same values for most of the data gathered in this survey; for these data the question of whether one or the other is the better average is hardly important. Even for those variables such as weight and the skin-folds, for which the differences are largest, the differences are not substantial.

3. The standard deviation. The standard deviation is the basic measure of variability. If most of a set of data cluster close to their mean value, the standard deviation is small. If, on the other hand, many of the data are either much smaller or much larger than the mean, the standard deviation will be large. By definition, the standard deviation is the square root of the average (i.e., arithmetic mean) of the squared deviations from the mean value. In formula, the standard deviation equals

$$SD = \sqrt{\Sigma(x-\bar{x})^2/N}$$

where  $\Sigma$  is the summation operator,  $x$  represents the individual values,  $\bar{x}$  their arithmetic mean, and  $N$  the number of values.

A useful way of conceptualizing the standard deviation is to consider the middle two-thirds of a set of data such as the values of stature. The smallest value in this middle two-thirds will be about one standard deviation below the mean value and the largest value in this set will be roughly equal to the mean value plus one standard deviation. Similarly, the middle 95 percent of the data will have values ranging from approximately two standard deviations below the mean to two standard deviations above it. Almost all of them will fall within the range from three standard deviations below the mean to three standard deviations above it.

The standard deviation is usually designated by SD or  $\sigma$ . Like the symbols for the mean, any one of these symbols may be subscripted when several variables are being considered at the same time.

4. The coefficient of variation. This statistic is a restatement of the standard deviation as a percent of the mean, and it is usually denoted by the letter V. Thus,

$$V = 100 \cdot SD/\bar{x}$$

The relationships which were noted for the standard deviation have equivalent forms in terms of V. Thus, about two-thirds of a set of data will lie between  $(100-V)\%$  and  $(100+V)\%$  of the mean, about 95 percent will lie between  $(100-2V)\%$  and  $(100+2V)\%$  of the mean. Rarely will values lie outside of the range from  $(100-3V)\%$  to  $(100+3V)\%$  of the mean.

For many anthropometric variables, the coefficient of variation varies within a much narrower range than does the standard deviation. The value of V is often associated with the general anatomical nature of the variable involved. Long bone lengths (major heights, hand length, and so forth) tend to have coefficients of variation in the range from 3.5% to 5%, fleshly circumferences have ones which range from 6% to 10%, and those for the skinfolds are mostly in the 30% to 40% range.

5. The percentiles. This group of statistics belongs to a class of measures designated as "measures of order or position." These measures can be thought of as being obtained by arranging the data in order from the smallest value to the largest one and then observing the value of the datum which lies at a specified position in the array.

Perhaps the most useful of these order statistics are the percentiles. The 99 percentiles--ranging from the first to the 99th--are the values at the points which separate consecutive blocks or units of 1% of the data in the ordered array. The first percentile is the value which separates the smallest 1% of the data from the 99% of the data with larger values; the second percentile separates the smallest 2% from the larger 98% and so on.

Twenty-five of these percentiles: the 1st, 2nd, 3rd, 5th, 10th, 15th, 20th, 25th, 30th, 35th, 40th, 45th, 50th, 55th, 60th, 65th, 70th, 75th, 80th, 85th, 90th, 95th, 97th, 98th, and 99th were computed for each of the measurements made on the full sample. For the sub-series measurements, the first and last three of the percentiles were omitted because of the small sample size.

The percentiles differ from the other statistics used in this report in that there is rarely a unique value satisfying the exact definition of the percentiles. Any method of computation of the percentiles of necessity requires some compromise with the definition, and the method of computation becomes the de facto definition. The method used here is described in detail several paragraphs later in the report.

6. Veta I - a measure of symmetry. The interpretation of the statistic  $B_1$  is based on the fact that in a symmetric distribution every value lying a given distance above the mean will be matched by a value lying an equal distance below the mean, so that the cubes of the deviations from the mean--half negative and half positive--will add to zero. Although the converse of this fact is by no means true--a zero sum of the cubed deviations in no way implies a symmetric distribution--the size of this sum when properly adjusted is often considered a useful indication of whether a set of data is unsymmetrically distributed and, if so, how badly. Such a use seems reasonably justified for the kind of data reported here.

Veta I is computed from the sum of the cubed deviations by dividing it by the sample size and the cube of the standard deviation, producing a dimensionless statistic:

$$B_1 = \frac{\sum (x - \bar{x})^3}{N \cdot SD^3}$$

7. Veta II - a measure of kurtosis. The statistic  $\beta_2$  is similarly computed from the fourth powers of the deviations:

$$\beta_2 = \frac{\sum(x-\bar{x})^4}{N \cdot SD^4}$$

The interpretation of  $\beta_2$  is not obvious; its major usefulness, along with  $\beta_1$ , is that its value provides a basis for judging the level of agreement between the normal distribution and the actual distribution of the data.

The normal distribution values for  $\beta_1$  and  $\beta_2$  are 0 and 3. In theory, data distributions can deviate from either of these values without deviating from the other. For the data of this study, however, deviant values of either  $\beta_1$  or  $\beta_2$  are usually accompanied by deviant values of the other. Most of these deviant values indicate positive skewness ( $\beta_1 > 0$ ) and platykurtosis ( $\beta_2 > 3$ ).

When we have occasion to spell out the symbol ' $\beta$ ' we have used 'Veta' in accordance with contemporary Greek pronunciation.

8. The standard errors. All statistics computed from a sample of data are subject to the effects of sampling error. When a sample has been selected by a random or other probability sampling process, it is often possible to estimate the magnitude of the sampling error. For many statistics, this estimate takes the form of the standard error of that statistic. The standard error is a standard deviation type statistic and is such that, were a large number of samples of data selected in the same way from the same population, about two-thirds of the samples would have means (or standard deviations or percentiles or whatever) with values which lie within a standard error of the corresponding population statistic, 95% within two standard errors, and so forth. Hence, it is conventional to suppose, when dealing with the statistics computed from a single sample, that the population statistics may well be within a standard error--up or down--of the corresponding sample statistics, and that it is rather likely that they are within two standard errors.

9. The frequency tables. The frequency tables group the data for each variable into a table containing up to fifty intervals. For most of the variables, except those with the smallest ranges the data were grouped in intervals 5 millimeters or 10 millimeters wide, the lower limits of these intervals always having values which end in 2.5 millimeters or 7.5 millimeters in order to minimize the effect of any overuse of the 0's or 5's as final digits.

The tables list, for each interval, the end points of the interval; the number of subjects whose measurement falls within the interval (FRQ); the cumulative frequency (CUMF), that is, the number whose measurement did not exceed the upper end point of the interval, and the values of FRQ and CUMF expressed as percentages of the total number measured (FRQ% and CUMF%).

The frequency tables appear in Appendix A.

10. The range. The range of values for a single variable constitutes a simple but, in general, highly erratic statistic. We have not included the range in the statistical summaries provided in the next several chapters, but the smallest ten and the largest ten values of each variable are listed in the XVAL printouts. The extent to which a single individual in a sample of over a thousand can seriously affect the range is well illustrated in Appendix B. Subject #92, for example, is not only solely responsible for a 58-pound (from 130 to 188 pounds) increase in the range of weights, but has also inflated the range for many of the circumferential measurements. Subject #246 has had a similar, but not so drastic, effect on the ranges of stature and a number of other height measurements.

The means, standard deviations, their standard errors and the percentiles are reported in both metric units (centimeters and kilograms) and in English units (inches and pounds). The frequency tables are given in the units in which the data were recorded.

#### Computational Procedures

The data obtained in the survey were initially recorded on the survey blanks illustrated in Figures 1-5. The data processing began with the transferring of the data from the survey sheets to punch cards. A total of four cards was used for each subject's data, one card for the background data, and three cards for the measured anthropometric data; single cards were used for each of the subseries. The data were subjected to two separate punchings and the resulting decks compared, column by column, on a computer. A computer printout provided a list by subject and variable number of any discrepancies between the two punchings. This procedure was believed to provide a more rigorous check than that of the more conventional use of a verifier.

The anthropometric data were recorded and punched in millimeter or tenth-of-pound figures. All data, except for the workspace and strength subseries, were punched as three digit values, initial 'fourth digit' values being ignored; these ignored values were reconstructed later as the data were transferred from cards to tape. For variables such as stature which exceeded one meter for all subjects, a value of 1000 was automatically added to each punched value. For

those variables, such as sitting height, which range in value from below 1000 millimeters to above 1900 millimeters, the correction of 1000 was added to the punched value if it was less than 400 and not otherwise. The initial digit for weight was established by reference to the subject's buttock circumference. The relatively small range of values for most of the measurements made it possible to reconstruct this initial digit without ambiguity. Data from the workspace and strength subseries were punched as four digit numbers. The background data were coded using the codes listed in Appendix C.

The punched cards were read into a computer and transferred to magnetic tape. The data analysis was carried out continuously as the records were received. As soon as the first group of records had been punched, the data analysis was begun. Summary statistics for this group were prepared and evaluated in an attempt to determine if unusual difficulties were being encountered by the measuring team. As additional records were punched, the tape record of the survey was updated and the editing process begun.

The editing process consisted of checking the values for each variable for each subject in order to detect any possible errors that might have occurred in the gathering-recording-transcription process. Two separate computer routines have been developed for this purpose. The first termed XVAL (=eXtreme VALue), determines for each variable the values which fall in the lower and upper extremes and which appear inconsistent with the other values for that variable. This program provides for each variable:

1. A list of the ten largest and ten smallest values with the associated subject numbers.
2. The mean, the standard deviations,  $\beta_1$  and  $\beta_2$  based on all the data.
3. The mean and the standard deviation estimated from the sample truncated by excluding the ten largest and ten smallest values.

Values which are far out of line with respect to the rest of the values for the variable are thereby identified and printed out for careful screening. The size of the smallest or largest values are often clear indicators of gross errors as are any substantial differences between the two sets of standard deviations. The measures of kurtosis,  $\beta_2$ , also effectively indicate the presence of values lying outside the 'normal' range.

XVAL printouts for the core measurements and the four subseries are listed in Appendix B (1-5). All values printed out as 'outliers' were investigated and errors corrected. The data were then subjected to the second of the editing routines, termed EDIT.

This routine is designed to evaluate each value in terms of other values recorded for the same individual through the use of a series of regression equations. The computer first calculates regression equations for each variable in a number of specified three-variable combinations in terms of the other two variables in that combination. Once these equations were available they were used to estimate each variable in the combination. The estimates were then compared to the measured values and if the difference exceeded 3.5 times the standard error of estimate, an error message was printed out. The error message consisted of the subject number, the variable name, observed value, estimated value, the difference between these two in standard error units, and a series of other measurements on that subject expressed both in measured units and in standard score form. The choice of combinations used with this program was based on the rule that at least one member of the triplet should be predictable, with fair accuracy, from the other two. A list of some of the combinations used in editing the core measurements appears in Table 11.

In general, when the results of EDIT indicated clearly that a value was in error and there was general agreement from other measurements as to what the correct value was, an appropriate change was made.

Initially the core measurements and the four subseries were edited separately. For the final editing runs on the subseries, some of the core measurements were combined with the subseries data.

The substantial number of dimensions measured on each subject, plus the high level of intercorrelations among the variables, make these approaches effective in evaluating each observation both in terms of all the values recorded for a variable and in terms of the values recorded for each subject. A handful of missing values occurred in the data. Many of these were the result of landmarks being covered with bandages or, in a couple of cases, of wigs which the subject would not remove, thus making the measurement of head circumference inexact. Regression estimates, based on related variables, were occasionally entered in order to provide full data records. Subjects for whom substantial numbers of measurements were missing were removed from the sample.

When the data were fully edited, a number of adjustments, required because of the way the data had been recorded, were made. Crotch and popliteal heights, for example, had been recorded as the height at the bottom of the anthropometer blade; one centimeter, the thickness of the blade, was added to these values. Five millimeters, half the thickness of the blade, was added to elbow-grip length. The thickness of the anthropometer stand was subtracted from functional leg length and the height of the sitting surface from overhead reach, sitting. These adjustments were delayed until this point in the analysis so that the values in the computer files would be, in general, the same as those on the data blanks until the editing was completed.

TABLE 11

3. Foot length, instep length, foot breadth
4. Heel breadth, foot breadth, foot circumference

The summary statistics reported here were calculated using a computer program essentially the same as that listed in Table II of Anthropometry of Army Aviators--1970 (Churchill, E., J. T. McCownville, L. L. Laubach and R. M. White. Anthropometry of U. S. Army Aviators--1970. Technical Report 72-52-CE, U. S. Army Natick Laboratories, Natick, Massachusetts, 1971. AD 743 528). This program makes use of four constants for each variable:

- A(I,1) - the bottom of the first interval in the frequency table for the I'th variable,
- A(I,2) - the maximum value attained by the I'th variable,
- A(I,3) - the whole number closest to the mean value of the I'th variable, and
- WID(I) - the desired width of the intervals in the frequency table.

The first of these constants was equal to or slightly less than the minimum value of the I'th variable; as the data were read into the computer they were routinely checked to insure that they fall within the range determined by A(I,1) and A(I,2).

The third constant was subtracted from each datum in order to reduce the size of the summations, particularly those required for the computation of  $B_1$  and  $B_2$ .

The fourth constant was used in constructing the frequency tables and hence in the computation of the percentiles.

These four constants were generated by the EVAL program and were stored, along with the variable names and conversion constants, on the data tape.

The computation of the mean, standard deviation, and the measures of symmetry and kurtosis are straightforward, as is the creation of the frequency tables.

The percentile computations are a bit complicated. They follow a procedure originally developed for use with a North Atlantic Treaty Organization (NATO) sponsored survey of military groups in Turkey, Greece, and Italy in 1960-1961. This procedure has been used with all large Department of Defense anthropometric surveys since then. The essence of the method is that the twenty-five percentiles which are to be listed are estimated using the textbook method; that is, the K-th percentile,  $P(K)$ , is estimated by locating the first interval in the frequency table in which the cumulative percent frequency equals or exceeds  $K\%.$

$$P(K) = LL + \frac{K - CPF(J-1)}{CPF(J) - CPF(J-1)} * WID$$

where LL is the lower limit of this interval, CPF(J) the cumulative percent frequency including this interval, CPF(J-1) the cumulative percent frequency up to but not including this interval, and WID is the interval width.

The twenty-five estimated percentiles are then smoothed by a process designed to simulate plotting them on normal probability graph paper and drawing a smooth line through the set of points. What is actually done is to assign an 'X-value' to each percentile estimate equal to the corresponding deviate of the normal distribution, to fit a fourth degree polynomial to these points, and to read the smoothed values from this polynomial. By using orthogonal polynomials, the computational procedure is fairly simple. Because of the size of the subseries samples, the extreme percentiles may not be particularly accurate; we have, therefore, listed only those from the 5th to the 95th.

Most of the summary statistics were multiplied by 0.1 to convert them from millimeters to centimeters; these values were in turn multiplied by 0.3937 to provide answers in inches. Weights and strength values were similarly multiplied by 0.1 to change them to pounds and then by 0.4536 to provide values in kilograms. To facilitate preparing the tables for photographic reproduction, the results were punched on cards and the tables as published were constructed from the cards.

## Chapter III

### STATISTICS FOR THE CORE MEASUREMENTS

The statistical tables in this chapter summarize the data for the basic series of 69 measurements which were made on all the survey subjects wearing bras and panties.

The series of core measurements were made up of:

- a. weight
- b. 11 standing height measurements
- c. 4 sitting height measurements
- d. 6 torso breadths and depths
- e. 8 torso (including the neck) circumferences
- f. 5 arm circumferences
- g. 4 leg circumferences
- h. 11 torso surface measurements
- i. 4 arm or arm-segment lengths
- j. 3 head measurements
- k. 4 hand measurements (not including the wrist)
- l. 7 foot measurements (not including the ankle)
- m. 1 leg-segment length

All unilateral measurements were made on the right side of the body, the right arm, or the right leg.

Age and other background material for the total group of women have been given in Chapter I.

These tables include, for each measurement, a brief definition, the mean, the standard deviation, the coefficient of variation,  $S_1$ , the coefficient of symmetry,  $S_2$ , the coefficient of kurtosis, the standard errors of the mean and the standard deviation, and 25 percentiles ranging from the first to the 99th. The frequency distributions appear in Appendix A. The printout of the XVAL program, appearing in Appendix B, provides, among other things, a listing of the ten smallest and the ten largest values for each measurement.

## Chapter IV

### STATISTICS FOR SUBSERIES 1: TRADITIONAL ANTHROPOMETRY

The first of the subseries consisted of 24 standard body size measurements and four skinfold measurements. These measurements were made on a subsample of 255 women who are compared, in terms of rank, age, race, stature, and weight, with the total sample in Table 12. As is indicated in this table, the subsample is trivially shorter (0.5 centimeters) and lighter (0.7 kilograms) than the total sample.

The 24 body size measurements included in this group were, for the most part, measurements deemed of importance almost equal to that of the core measurements. A number of these measurements were essentially the same as measurements in the core series except that they were made with the body or body segment in a different position—the subject sitting rather than standing or the arm flexed rather than relaxed, for example—or were based on somewhat different landmarks. All 24 were judged to be highly related to measurements in the core series. It is, therefore, possible to adjust the summary statistics for these variables to provide reasonable estimates of the values which would have been obtained had this subseries been measured on the total sample.

Sixty of the 24 measurements were standing heights and one a sitting height. These measurements combine with the heights in the core series to provide a total of 19 standing and five sitting heights. Three subseries measurements: acromion-radiale, radiale- scylior, and elbow-grip lengths, join with shoulder-elbow and elbow-finger-tip lengths to constitute a set of five arm-segment lengths. Four major breadths: bitemporal, bispinous, abdominal-extension, and thigh-thigh, are added to the four breadths in the core series to describe more fully the widths of the body. Three major circumferences, measured in the core series, were remeasured with the subject sitting rather than standing (hip, vertical trunk) or using a different landmark (waist). Axillary arm circumference complements, in a way, the core measurement of arm scye circumference, as biceps and forearm circumferences, measured with the arm flexed, complement the arm circumferences measured with the arm relaxed. Abdominal extension depth and thigh cleavage complete the list of the standard measurements in this subseries.

The four skinfold thickness measurements were made using Lange skinfold calipers on triceps, biceps, subscapular, and suprailiac sites. Like all other unilateral measurements, the skinfolds were measured on the right side of the subject.

TABLE 12  
CHARACTERISTICS OF TRADITIONAL ANTHROPOOMETRY SUBSAMPLE  
AND TOTAL SAMPLE

<u>a. Rank</u>	<u>Subsample</u>		<u>Total Series</u>

## Chapter V

### STATISTICS FOR SUBSERIES 2: THE WORKSPACE MEASUREMENTS

The workspace subseries consisted of 14 measurements closely patterned on the measurements made by Milton Alexander and C. E. Clauser (1965) in their Air Force study of the anthropometry of common working positions of male missile workers (The Anthropometry of Common Working Positions, AFRL-TR-65-73, Aerospace Medical Research Laboratory, Wright-Patterson Air Force Base, Ohio, 1963). The present study, based on 300 subjects, could appear to be the first reporting of measurements of this general type on women in the U. S. military services.

For these measurements the subjects wore their normal indoor clothing. For most subjects this clothing included fatigues and boots, although 31 subjects (all but one of those measured at Kitter Reed Medical Center) were measured while wearing slacks and shoes. The subjects wearing fatigues and boots weighed roughly 5 kilograms more than their essentially nude weights; the subjects in slacks and shoes increased their weights about 3 kilograms. Both boots and shoes added approximately 3.5 centimeters to the measured stature.

This subseries, as has been described in the discussion of survey methodology and measuring techniques, made extensive use of graph paper attached to a wall and to the floor and required a corner in which the subject could stand with her back against one wall and her arm extended along a second wall at right angles to the first one. At one of the measuring sites (Fort Sam Houston), no such corners existed in the building assigned to the survey. As a consequence, no measurements of this subseries were made there. At Kitter Reed Medical Center, the floor of the measuring room was carpeted and a piece of standard size plywood was used as the "floor" for these measurements.

A comparison of the subsample on which these measurements were made with the total sample in terms of rank, age, race, stature, and weight is given in Table 13.

The tables in this chapter follow the pattern of those in the two previous chapters. Frequency distributions for these data are in Appendix A and their 75th percentile in Appendix B.

TABLE 13  
CHARACTERISTICS OF WORKSPACE SUBSAMPLE AND TOTAL SAMPLE

<u>a.</u>	<u>Rank</u>	<u>Subsample</u>	<u>Total Series</u>
	0-4 to 0-6	2	3%

## Chapter VI

### STATISTICS FOR SUBSERIES 3: THE HEAD AND FACE MEASUREMENTS

A total of 31 head and face measurements constituted Subseries 3. Sixteen, or just over half, were measurements made using the head-board, 10 were made with calipers, and five were tape measurements. The subsample consisted of 215 women.

The headboard measurements (see Figure 6) included measurements from the back and the top of the headboard to the chin (mentor), the base of the nose (subnasale), the tip of the nose (pronasale), nasal root depression (sellion), the outer corner of the eye (ectocanthus), the forehead (glabella), and the notch just forward of the ear hole (tragion). The distance from the top of the headboard to the mouth was made to stomion, the point in the midsagittal plane in which the lips come together, whereas the corresponding horizontal measurement from the back of the head was made to the most forward point in the plane of the lips.

Three of the caliper measures were made in the profile or mid-sagittal plane: from the nasal root depression to the chin (face length: sellion-menton); from the nasal root depression to the base of the nose (nose length: sellion-subnasale), and from the hairline (crinion) to the chin (menton). The other seven measurements are breadths: biorcular, interpupillary, mouth (smiling), nose, face (bizygomatic), bitragion, and zygion-frontal.

All five tape measurements were arcs measured with the lips passing variously over the top of the head from front to back and from right to left: tragion over the top of the head, across the forehead, under the chin or under the gonial angle of the chin.

Three head measurements were included in the core series: head breadth, head length, and head circumference. We have included the summary statistics for these three measurements as based on the subsample in the statistics given in this chapter.

A comparison of the head-face subsample with the total sample with respect to race, age, and race is given in Table 14. Rather than include stature and weight in this comparison, as we did in Tables 12 and 13, we have shown the contrasting values for head length, head breadth, and head circumference. The circumferences differ by about one millimeter in their mean values; the length means and breadth means show almost no differences. Frequency distributions for these data are in Appendix A and their XVAL printout in Appendix B.

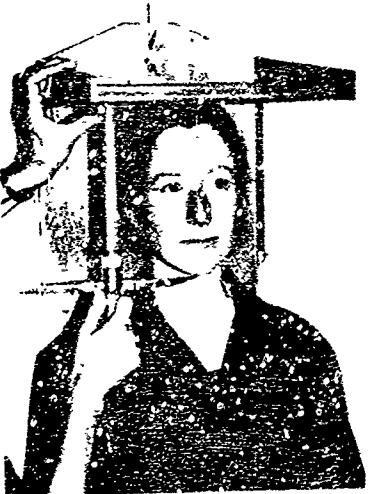

Figure 6. Headboard.

TABLE 14

## CHARACTERISTICS OF HEAD AND FACE SUBSAMPLE AND TOTAL SAMPLE

## Chapter VII

### STATISTICS FOR SUBSERIES 4: THE STATIC STRENGTH MEASUREMENTS

Nine sets of static strength measurements were made on a subsample of 349 women dressed in normal indoor apparel. These measurements were made using the strength monitor developed by the Department of Industrial and Operations Engineering of the University of Michigan in Ann Arbor (Chaffin, D.K. "Ergonomics Guide," American Industrial Hygiene Association Journal, July 1975). This monitor is illustrated in Figure 7.

Six of these measurements were two-handed pulls, four of which were made with the subject standing and using the long handle (Figure 7A); the other two were made with the subject seated and using the short handle (Figure 7F). The distance between the center of the grips was 45 centimeters for the long handle and 15 centimeters for the short handle. The other three measurements were one-handed pulls made using a D-ring (Figure 7C). The grips of both handles and the D-ring were metal cylinders about 2.5 centimeters in diameter around which several layers of tape were wound. All measurements were made at fixed distances above the floor.

Forces were measured in pounds with a strain gauge and recorded and displayed on a lifting force meter. The meter is a digital voltmeter with circuitry that records a peak and a time-averaged strength score.

The average, or mean, force was obtained by evaluating the sensed force over a 3.0 second interval. This interval began 2.0 seconds after the force reached a minimum value of 10 pounds (4.5 kilograms) providing that at this time the force still exceeded this minimum. The maximum value given by the monitor was the highest value observed during the entire period in which a force was being exerted.

The nine sets of measurements were not made, as a rule, in the order in which they appear in the survey blank (Figures 5a and 5b). Because of the time and labor required in switching the handles and the D-ring, each subject started with the arrangement with which the previous subject finished. This procedure had the advantage of substantially spreading any effects of novelty and fatigue over the full set of measurements. Each measurement was made twice, each repeat measurement usually following the original one after a brief pause to allow the subject to rest. Both sets of measurements were recorded and appear in the summary statistics as MEAN FORCE 1 and 2 and PEAK FORCE 1 and 2. On a number of occasions, two or three subjects were run through these tests together. When this was the

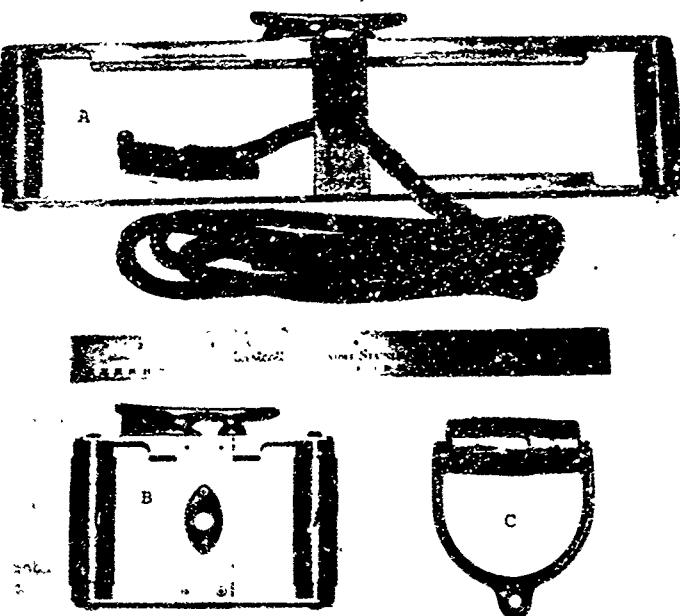

Figure 7. Strength-measuring handles:  
A - long handle; B - short handle;  
C - D-ring.

case, both (or all three) subjects were measured once in a particular arrangement after which the repeat measurements were made with the same subject sequence. This practice of running two or three subjects at a time considerably decreased the amount of measurer time per subject, while providing a substantial rest period between original and repeat measurements.

Members of the total sample were assigned to this subseries on a more-or-less haphazard basis. Subjects who wished not to participate in the strength measurements were free to withdraw and a few did decline to take part. One subject, while nominally participating, indicated by her attitude and her measurements that she was making no real effort, and her data were discarded.

Subjects were measured wearing their normal indoor clothing which generally included fatigues and boots. Unlike the practice followed throughout the rest of the study of always making unilateral measurements on the subject's right side, the three one-handed strength measurements were made using the subject's dominant hand—as determined by direct inquiry—and on the corresponding side of the body.

The summary statistics are presented in the next several pages in a somewhat different format than that used in the preceding chapters. For both mean strength and peak strength values, the means ( $M$ ), standard deviations ( $SD$ ), coefficients of variation ( $V$ ), measures of symmetry ( $V-I$ ) and kurtosis ( $V-II$ ), and the 11 percentiles judged most relevant (5th, 10th, 15th, 25th, 35th, 50th, 65th, 75th, 85th, 90th, and 95th) are listed. The means and standard deviations are listed in pairs, the initial value being in kilograms followed, after a slash, by the pound value.

In reporting the strength data, the conventional units of kilograms and pounds have been used. However, in accordance with the International System of Units, generally known as SI, the correct unit for reporting kilograms or pounds of force is the newton. The kilogram-force values reported here may be converted to newtons by multiplying by 9.806, while the pound-force values may be converted to newtons by multiplying by 4.468.

A comparison of the strength subsample with the full sample in terms of rank, race, age, weight, and stature appears in Table 15. Frequency distributions for these data are in Appendix A and their XVAL printout in Appendix B.

TABLE 15  
CHARACTERISTICS OF STATIC STRENGTH SUBSAMPLE AND TOTAL SAMPLE

	<u>Subsample</u>	<u>Total Series</u>
a. <u>Rank</u>		
0-4 to 0-6	5 1%	3%
0-1 to 0-3	65 25%	23%

Both	12 4%	4%
Total	345 100%	100%

\* Background data was not available for four subjects in this subsample.

<sup>+</sup> Percentages based on those identified.

## STRENGTH STATISTICAL LISTINGS

Standing Two-Handed Pull: 38  
Centimeter Level

The subject stands with her feet 45 centimeters apart and her knees bent. She bends at the waist and grasps both sides of the long handle which is attached 38 centimeters above the platform and directly in front of her. She is instructed to minimize pull with her back to lessen the chance of injury. She attempts to lift the handle, primarily using the arms and shoulders but also using her legs by extending them upwards.

## STRENGTH, TWO HANDED PULL, AT 38CM

## STRENGTH STATISTICAL LISTINGS

Standing One-Handed Pull: 100  
Centimeter Level (D-Ring)

The subject stands erect with her feet 15 centimeters apart. With her dominant hand (right, if she has reported that she is ambidextrous), she grasps, from the underside, the D-ring which is attached 100 centimeters above the platform and at a point just to the right (or left, as is appropriate) of her body. She attempts to lift the D-ring, primarily using her arm while keeping her shoulders square, her feet firmly planted on the platform, and her other arm relaxed at her side.

## STRENGTH STATISTICAL LISTINGS

Seated Two-Handed Pull: Centerline  
of Seat, 38-Centimeter Level  
(Short Handle)

The subject sits erect with her feet 55 centimeters apart. She bends slightly at the waist and grasps both sides of the short handle which is attached 38 centimeters above the platform at a point just forward of the chair and in its vertical mid-plane. She attempts to lift the handle, primarily using her arms and shoulders while keeping her feet flat and her arms off her thighs.

STRENGTH STATISTICAL LISTINGS

Seated One-Handed Pull: Side of  
Seat, 45-Centimeter Level  
(D-Ring)

The subject sits erect with her feet 55 centimeters apart. With her dominant hand, she grasps, from the underside, the D-ring which is attached 45 centimeters above the platform and a short distance to the right (or left, as is appropriate) of the point midway between the maximal protraction of the buttock and knee. She attempts to lift the D-ring, keeping her shoulders square, her feet firmly planted on the platform, and her other arm resting in her lap.

STRENGTH, ONE HANDED FULL, SEATED-AT SIDE, AT -5CM

APPENDIX A  
FREQUENCY DISTRIBUTIONS FOR ALL MEASUREMENTS

A frequency table is given in this appendix for each set of measurement data. These are the tables used in the computation of the percentile values. Interval widths were chosen so that the number of intervals in each table did not exceed 50. Where appropriate, interval widths of five or ten millimeters were used; when this was done, the lower limits of the intervals were selected so that they had values ending in 0.25 centimeters or 0.75 centimeters to minimize the effect of any possible overuse of 0's or 5's as final digits. Measurement values were treated as though they extended over a range of from half a unit below the recorded value to half a unit above it. Because of this way of handling the data, the limits of the frequency table will exceed those of the recorded data at both ends of the scale. Actual recorded maximum and minimum values can be found in the XVAL printouts in Appendix B.

In each table, the actual frequencies are listed in the columns labeled FRQ, the cumulative frequencies in the columns headed CUMF, the frequencies expressed as percentages of the total count in the columns headed FRQ%, and the cumulative percents in the columns headed CUMFX.

APPENDIX B  
XVAL COMPUTER PRINTOUTS

The following pages contain computer printouts for the core series and each of the four subseries for the XVAL (=eXtreme VALUE) program. These printouts represent the data after the editing described in Chapter II had been completed.

These printouts provide, for each variable, the following values:

- a. the ten smallest values and the associated subject numbers;
- b. the ten largest values and the associated subject numbers;
- c. the mean value based on all the data;
- d. the standard deviation based on all the data;
- e. the coefficient of variation;
- f.  $B_1$ , the measure of symmetry;
- g.  $B_2$ , the measure of kurtosis;
- h. the mean value based on all the data except the 20 extreme values (those listed here): "(N-20)-AVG EST";
- i. the standard deviation estimated on the basis of all the data except the 20 extreme values (a truncated normal distribution is assumed): "(N-20)-S.D. FST";
- j. the difference between the two mean values (items c and h) expressed as a percent of the estimated standard deviation (item i);
- k. the difference between the two standard deviation values (items d and i) similarly expressed;
- l. the number of non-zero values.

The data values are in the units in which they were measured with a few exceptions. Most values are in millimeters. Skinfolds, although measured in millimeters, were recorded in tenths of millimeters. The static strength values are in tenths of pounds. The weights were measured to the quarter-pound and punched as tenths of pounds.

B-1. XVAL FOR THE CORE MEASUREMENTS

This XVAL printout covers the 69 core measurements as computed  
on the basis of the 1331 subjects.

B-2. XVAL FOR THE TRADITIONAL  
ANTHROPOMETRY SUBSERIES

This XVAL printout covers the 28 measurements made on a subsample of 255 subjects in the traditional anthropometry subseries (subseries #1). Included in this printout are data for waist height at omphalion and midshoulder height, sitting which are not reported elsewhere because they were measured only on the last 88 subjects in the subseries. Height and weight data for this subsample are also given in this printout. Following are the means, standard deviations, 5th and 95th percentile values for these additional variables:

	<u>Mean</u>	<u>S.D.</u>	<u>5th Zile</u>	<u>95th Zile</u>
Waist height, omphalion	98.2 cm	4.7	90.2	106.4
Midshoulder height, sit.	59.1 cm	2.8	54.4	63.5
Height	162.4 cm	6.4	151.9	173.1
Weight	130.5 lbs	19.7	101.1	161.6

#### B-4. XVAL FOR THE HEAD AND FACE SUBSERIES

This XVAL printout covers the 31 head and face measurements made on a subsample of 216 subjects. Comparative data are included for head length, head breadth, and head circumference, and for ear length, ear breadth, and biauricular breadth. These last three were measured on only the last 37 members of the head-face subseries and are not reported elsewhere. Summary statistics for these six additional measurements appear below.

	<u>Mean</u>	<u>S.D.</u>	<u>5th Zile</u>	<u>95th Zile</u>
Ear length	5.8 cm	0.4	5.2	6.3
Ear breadth	3.7 cm	0.3	3.2	4.1
Biauricular breadth	16.5 cm	0.7	15.2	17.3
Head circumference	55.0 cm	1.8	52.3	57.3
Head length	18.7 cm	0.7	17.5	19.6
Head breadth	14.6 cm	0.5	13.8	15.3

MEMORIALS AND CEREMONIES UPON SPECIALISTS IN THE ARMY

SUMMARY OF THE MATERIAL ALREADY PRESENT IN THIS JOURNAL, AND THE SUBJECTS CO-ON THE BUNCHEN RANGE CARDS

### B-5. XVAL FOR THE STATIC STRENGTH SUBSERIES

This XVAL printout covers the 36 measurements (two mean and two peak values at each of nine arrangements) made on a subsample of 349 subjects in the static strength subseries. The statures and weights of the members of this subsample are included here. Summary statistics for these two additional variables are listed below.

	<u>Mean</u>	<u>S.D.</u>	<u>5th Zile</u>	<u>95th Zile</u>
Stature	163.1 cm	6.2	153.6	174.1
Weight	132.5 lbs	19.1	103.4	162.3

## APPENDIX C

## THE CODING OF THE BACKGROUND VARIABLES

On the magnetic tape and punched card records of these data, the data for race, rank, birthplace, military occupation and handedness are in coded form:

1. Race: 1-White, 2-Black, 3-Oriental.
2. Rank: 1-E1 (Basic), 2-E2 (Private), 3-E3 (Private, First Class), 4-E4 (Corporal or Specialist 4th Class), 5-E5 (Sergeant or Specialist 5th Class), 6-E6 (Staff Sergeant or Specialist 6th Class), 7-E7 (Sergeant, First Class or Specialist 7th Class).  
11-01 (2nd Lieutenant), 12-02 (1st Lieutenant), 13-03 (Captain), 14-04 (Major), 15-05 (Lt. Col.), 16-06 (Colonel).
3. Birthplace:

<u>New England States</u>	<u>East North Central States</u>
11 Maine	41 Ohio
12 New Hampshire	42 Indiana
13 Vermont	43 Illinois
14 Massachusetts	44 Michigan
15 Rhode Island	45 Wisconsin
16 Connecticut	
<u>Mid-Atlantic States</u>	<u>East South Central States</u>
21 New York	51 Kentucky
22 New Jersey	52 Tennessee
23 Pennsylvania	53 Mississippi
	54 Alabama
<u>South Atlantic States</u>	<u>West North Central States</u>
31 Delaware	61 Minnesota
32 Maryland	62 Iowa
33 District of Columbia	63 Missouri
34 Virginia	64 North Dakota
35 West Virginia	65 South Dakota
36 North Carolina	66 Nebraska
37 South Carolina	67 Kansas
38 Georgia	
39 Florida	
<u>West South Central States</u>	
	71 Arkansas
	72 Louisiana
	73 Oklahoma
	74 Texas

Mountain States

- 81 Montana
- 82 Idaho
- 83 Wyoming
- 84 Colorado
- 85 Utah
- 86 Nevada
- 87 Arizona
- 88 New Mexico

Pacific States

- 91 California
- 92 Oregon
- 93 Washington
- 94 Alaska
- 95 Hawaii

Foreign

- 01 Canada and English speaking  
Caribbean Islands
- 02 Mexico, Central America,  
Panama and non-English speaking  
Caribbean Islands
- 03 South America
- 04 Europe, excluding the Mediterranean  
countries
- 05 European Mediterranean countries
- 06 Africa
- 07 Asia
- 08 Australia, New Zealand, Oceania

4. Military Occupation

a. Enlisted Women:

- 01 Medical laboratory technicians (mainly 92B, 92B10,  
92B20)
- 02 Medical assistants, nurses aides, etc. (mainly 91B,  
91C, 91B1G, 91B20, 91C10, 91C20, 91C40)
- 03 X-ray technicians (mainly 91P10)
- 04 Dental specialists (mainly 91E10)
- 05 Clerk typists (mainly 71B10, 71B20)
- 06 Pharmacy technicians (mainly 91Q)
- 07 Truck drivers, motor transport operators  
(mainly 64C10)
- 08 Traffic coordinators
- 09 Drill sergeants
- 10 Supply clerks (mainly 76Y10)
- 11 Military police (mainly 95B10)
- 12 Chaplain assistants (mainly 71M)
- 13 Cooks, food service (mainly 94F)
- 14 Medical records (mainly 71G)

- 15 Communications (mainly 31M)
- 16 Intelligence analysts (mainly 96B)
- 17 Finance clerks (mainly 73C)
- 18 Unit clerks (mainly 75B, 75C, 75D)
- 19 Photographers
- 20 Telephone repair persons and operators
- 21 Band
- 22 Data processors
- 23 Ammunition specialists
- 24 Cryptologists (mainly 98G)
- 25 Occupational therapists (mainly 65A, 91L)
- 26 Food inspectors (mainly 91R)
- 27 Miscellaneous health specialists (mainly 91A, 91F, 91G, 91J, 91N, 91S)
- 28 Operating room technicians (mainly 91D)
- 29 Electronics, radio, radar
- 30 Mechanics, welders, carpenters, etc.
- 31 Miscellaneous undecipherable and not stated

b. Officers:

- 50 Nurses (mostly 66H, 66G, 66J, 3448, etc.)
- 51 Dietitians (mostly 65C, 3420)
- 52 Student Officers
- 53 Company commanders, training officers
- 54 Military police
- 55 Physical therapists (65B)
- 56 Miscellaneous and not stated

5. Handedness

- 1 right-handed, 2 left-handed, 3 ambidextrous,
- 4 no response.
